Water
8 Glasses A Day
Keeps the Fat Away

Water is probably the single, most important catalyst in losing weight and keeping it off. Although most of us take it for granted, water may be the only true "magic potion" for permanent weight loss.

Water suppresses the appetite naturally and helps the body metabolize stored fat. Studies have shown that a decrease in water intake will cause fat deposits to increase, while and increase in water intake can actually reduce fat deposits. Here's why. The kidneys can't function properly without enough water. When they don't work to capacity, some of their load is dumped onto the liver. One of the liver's primary functions is to metabolize stored fat into usable energy for the body. But, if the liver has to do some of the kidney's work, it can't operate at full throttle. As a result, it metabolizes less fat, more fat remains stored in the body and weight loss stops.

Drinking enough water is the best treatment for fluid retention. When the body gets less water, it perceives this as a threat to survival and begins to hold onto every drop. Water is stored in extracellular spaces (outside the cells). This shows up as swollen feet, legs and hands.

Diuretics offer a temporary solution at best. They force out stored water along with some essential nutrients. Again, the body perceives a threat and will replace the lost water at the first opportunity. Thus, the condition quickly returns. The best way to overcome the problem is to give your body what it needs — plenty of water. Only then will the stored water be released.

If you have a constant problem with water retention, excess salt may be to blame. Your body will tolerate sodium only in a certain concentration. The more salt you eat, the more water your system retains to dilute it. But getting rid of unneeded salt is easy — just drink more water! As it is forced through the kidneys it takes away excess sodium.

The overweight person needs more water than the thin one. Larger people have larger metabolic loads. Since we know that water is the key to fat metabolism, it follows that the overweight person needs more water.

Water helps to maintain proper muscle tone by aiding the muscles natural ability to contract and by preventing dehydration. It also helps to prevent the sagging skin that usually follows weight loss. Shrinking cells are buoyed by water, which plumps the skin, leaving it clear, healthy and resilient.

Water helps rid the body of waste. During weight loss, the body has a lot more waste to get rid of — all that metabolized fat must be shed. Again, adequate water helps flush out the waste.

How much water is enough? On the average, a person should drink eight 8 ounce glasses every day. That's about 2 quarts. However, the overweight person needs one additional glass for every 25 pounds of excess weight. The amount you drink also should be increased if you exercise briskly or if the weather is hot and dry.

Water should preferably be cold — it's absorbed into the system more quickly than warm water. And some evidence suggests that drinking cold water can actually help burn calories! When the body gets the water it needs to function optimally, it's fluids are perfectly balanced. When this happens, you have reached the "breakthrough point." What does this mean?

◆ Endocrine gland function improves.
◆ Fluid retention is alleviated as stored water is lost.
◆ More fat is used as fuel because the liver is free to metabolize stored fat.
◆ Natural thirst returns.
◆ There is a loss of hunger almost overnight.

If you stop drinking enough water your body fluids will be thrown out of balance again, and you may experience fluid retention, unexplained weight gain and loss of thirst. To remedy this situation you'll have to go back and force another "breakthrough."
